

WART and its treatment with Homoeopathy

A wart is a small, non-cancerous skin growth caused by the human papillomavirus (HPV). The virus causes an excess of keratin (a hard protein) to build up in the top layer of the skin, creating a rough, raised bump.

Some terminology :

VERUCCA : A **verruca** is the medical term for a wart. In British English, it most specifically refers to a plantar wart—a small, hard, infectious growth that appears on the sole of the foot. Verrucas are caused by the Human Papillomavirus (HPV) and are highly contagious in moist communal spaces like swimming pools and locker.

Locomotor System : The **locomotor system**, also known as the musculoskeletal system, is the organ system that gives your body the ability to move, stand, and interact with the environment. It provides form, stability, and support while protecting vital internal organs.

Condyloma : **Condyloma** refers to soft, benign (noncancerous) growths or warts on the skin or mucous membranes of the genital or anal area, often appearing as cauliflower-like bumps. Primarily caused by the human papillomavirus (HPV), they are highly contagious sexually transmitted infections (STIs).

Condylomata : **Condylomata** (plural of *condyloma*) is the medical term for wart-like growths on the genitals or around the anus. The term is divided into two main categories:

Fig Warts : "Fig warts" is an archaic or literal translation (from German *Feigwarze*) for **genital warts**, which are small, soft, often cauliflower-shaped growths caused by the Human Papillomavirus (HPV). They appear in the genital or anal areas and are considered a sexually transmitted infection (STI).

In homoeopathy, warts are considered localized symptoms of an underlying constitutional or systemic imbalance rather than just isolated skin issues. Rather than prescribing topical applications or removing the wart surgically, homoeopaths aim to stimulate the body's natural immune response to clear the human papillomavirus (HPV) from within.

Wart is one of the common dermatological disorders caused by DNA viruses, which grow in the epidermis. The source of infection is other infected individuals and the disease is transmitted by direct or close contact. It has very low infectivity; a casual contact with an infected individual is unlikely to result in the disease. The virus enters into the skin through minor or microscopic injuries. Clinically the lesions are asymptomatic and manifest in different forms, have irregular verrucous surface and keep on growing slowly. The number of warts varies from single to several hundred. The individuals with depressed cell-mediated immunity due to treatment with immunosuppressive drugs, Hodgkins'disease, malignant lymphomas and lymphocytic leukaemia are more likely to have a large number of warts.
